PROJECT FLOW

Customer Onboarding Throughput Transformation

Executive Decision Brief | Reporting period: October 2025 – September 2026

Executive summary

Project FLOW analyses a 12-month synthetic onboarding dataset to identify operational delays, quantify rework, evaluate workload distribution and support evidence-based process improvement decisions. The work uses SQL validation, Excel decision modelling and a four-page Power BI report.

Baseline

Received	Completed	Closing backlog	SLA attainment
2,508	2,167	360	49.2%
Mean cycle time	**Median cycle time**	**P90 cycle time**	**Qualifying rework**
40.8 days	35.1 days	70.0 days	530 apps / 571 events

Evidence-supported findings

• **Service level:** 49.2% of eligible completed cycles met the 35-calendar-day SLA, indicating inconsistent performance against the baseline target.

• **Bottleneck signal:** Finance Approval ranks first in the supplied composite analysis; mean queue time is approximately 1.43 days. This is a prioritisation signal, not proof of sole or causal responsibility.

• **Rework:** 530 applications with qualifying rework among 2,665 eligible applications (19.9%); 571 qualifying events. Driver minutes are effort proxies and must not be summed across dimensions.

Recommended decision

Prioritise a controlled investigation and pilot around Finance Approval while examining upstream handoff quality and leading rework drivers. Candidate controls include complete evidence checks, standard exception reasons, queue-age visibility and defined escalation ownership. Select an intervention option only after reviewing the corrected Excel model's throughput, gap to 240, staffing, costs, sensitivity and implementation feasibility.

Success measures

Predefine observation window, eligibility rules and thresholds for monthly receipts/completions, closing backlog, calendar-day cycle time, 35-day SLA attainment, rework rate, qualifying rework effort and workload indicators.

Scope and limitations

This is a portfolio case study using synthetic data. The Power BI implementation contains four pages: Executive Report, Process Bottlenecks, Quality & Rework, and Capacity & Workload. The planned Intervention Scenarios page has not been built; scenario comparison remains in Excel. The future-state workflow and RACI/SOP are proposed designs. Modelled outcomes are projections, not realised savings, and no causal improvement claim should be made without pilot evidence.

Prepared as a business analysis and operational improvement case study.
